(57) **ABSTRACT**

A method, an apparatus, and a computer program product for wireless communication are provided in which a system timing is estimated, derived from timing of one or more cells, a timing offset is determined for a plurality of cells relative to the estimated system timing, and signals received from the plurality of cells are processed using the timing offsets. In addition, a method, an apparatus, and a computer program product for wireless communication are provided in which a carrier frequency is estimated, derived from a frequency of one or more cells, a frequency offset is determined for a plurality of cells relative to the estimated system timing, and signals received from the plurality of cells are processed using the frequency offsets.

PER-CELL TIMING AND/OR FREQUENCY ACQUISITION AND THEIR USE ON CHANNEL ESTIMATION IN WIRELESS NETWORKS

CLAIM OF PRIORITY UNDER 35 U.S.C. §119
AND §120

The present application for patent is a Divisional application of U.S. Ser. No. 12/949,020; filed Nov. 18, 2010, entitled "PER-CELL TIMING AND/OR FREQUENCY ACQUISITION AND THEIR USE ON CHANNEL ESTIMATION IN WIRELESS NETWORKS" which claims priority to U.S. Provisional Application No. 61/262,911, entitled, "PER-CELL TIMING AND/OR FREQUENCY ACQUISITION AND THEIR USE ON CHANNEL ESTIMATION IN WIRELESS NETWORKS," filed Nov. 19, 2009, and assigned to the assignee hereof and expressly incorporated herein by reference.

FIELD

The present disclosure relates generally to communication systems, and more particularly, to utilizing per-cell timing acquisition, per-cell frequency acquisition, or a combination thereof, for channel estimation in wireless networks.

BACKGROUND

Wireless communication systems are widely deployed to provide various telecommunication services such as telephony, video, data, messaging, and broadcasts. Typical wireless communication systems may employ multiple-access technologies capable of supporting communication with multiple users by sharing available system resources (e.g., bandwidth, transmit power). Examples of such multiple-access technologies include code division multiple access (CDMA) systems, time division multiple access (TDMA) systems, frequency division multiple access (FDMA) systems, orthogonal frequency division multiple access (OFDMA) systems, single-carrier frequency divisional multiple access (SC-FDMA) systems, and time division synchronous code division multiple access (TD-SCDMA) systems.

These multiple access technologies have been adopted in various telecommunication standards to provide a common protocol that enables different wireless devices to communicate on a municipal, national, regional, and even global level. An example of an emerging telecommunication standard is Long Term Evolution (LTE). LTE is a set of enhancements to the Universal Mobile Telecommunications System (UMTS) mobile standard promulgated by Third Generation Partnership Project (3GPP). It is designed to better support mobile broadband Internet access by improving spectral efficiency, lower costs, improve services, make use of new spectrum, and better integrate with other open standards using OFDMA on the downlink (DL), SC-FDMA on the uplink (UL), and multiple-input multiple-output (MIMO) antenna technology. However, as the demand for mobile broadband access continues to increase, there exists a need for further improvements in LTE technology. Preferably, these improvements should be applicable to other multi-access technologies and the telecommunication standards that employ these technologies.

SUMMARY

In some scenarios, a UE may need to connect to a weak cell instead of the strongest nearby cell. For example this may

2

occur during range expansion or where the strongest cell may be a closed subscriber group (CSG) cell. In such scenarios, it may be beneficial for the UE to track the timing, carrier frequency, or both of the stronger cell instead of the weaker serving cells. As a UE tracks a single timing (be it a serving cell's timing, a strong interferer's timing, or a composite timing), there naturally exists a gap between the timing the UE is tracking and the timing of each cell the UE wants to monitor.

In aspects of the disclosure, methods, apparatuses, and a computer program products for wireless communication are provided, generally involving estimating system timing, wherein the estimated system timing is derived from the timing of one or more cells, determining timing offsets, relative to the estimated system timing, for a plurality of cells, and processing signals received from the plurality of cells with channel tap truncation windows set based on the timing offsets.

In aspects of the disclosure, methods, apparatuses, and a computer program products for wireless communication are provided, generally involving estimating a carrier frequency, wherein the estimated frequency is derived from the frequency of one or more cells, determining frequency offsets, relative to the estimated carrier frequency, for a plurality of the cells, and processing signals received from the plurality of cells based on one or more of the frequency offsets.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a conceptual diagram illustrating an example of a hardware implementation for an apparatus employing a processing system.

FIG. 2 is a conceptual diagram illustrating an example of a network architecture.

FIG. 3 is a conceptual diagram illustrating an example of an access network.

FIG. 4 is a conceptual diagram illustrating an example of a frame structure for use in an access network.

FIG. 5 is a conceptual diagram illustrating an example of a radio protocol architecture for the user and control plane.

FIG. 6 is a conceptual diagram illustrating an example of an eNodeB and UE in an access network.

FIG. 7 is a conceptual diagram illustrating a UE receiving signals from a plurality of eNodeBs.

FIG. 8 is a flow chart of a method of wireless communication.

FIG. 9 is another flow chart of a method of wireless communication.

FIG. 10 is a conceptual block diagram illustrating the functionality of an exemplary apparatus.

FIG. 11 is a flow chart of a method of wireless communication.

FIG. 12 is another flow chart of a method of wireless communication.

DETAILED DESCRIPTION

The detailed description set forth below in connection with the appended drawings is intended as a description of various configurations and is not intended to represent the only configurations in which the concepts described herein may be practiced. The detailed description includes specific details for the purpose of providing a thorough understanding of various concepts. However, it will be apparent to those skilled in the art that these concepts may be practiced without these specific details. In some instances, well known structures and

components are shown in block diagram form in order to avoid obscuring such concepts.

Several aspects of telecommunication systems will now be presented with reference to various apparatus and methods. These apparatus and methods will be described in the following detailed description and illustrated in the accompanying drawing by various blocks, modules, components, circuits, steps, processes, algorithms, etc. (collectively referred to as “elements”). These elements may be implemented using electronic hardware, computer software, or any combination thereof. Whether such elements are implemented as hardware or software depends upon the particular application and design constraints imposed on the overall system.

By way of example, an element, or any portion of an element, or any combination of elements may be implemented with a “processing system” that includes one or more processors. Examples of processors include microprocessors, microcontrollers, digital signal processors (DSPs), field programmable gate arrays (FPGAs), programmable logic devices (PLDs), state machines, gated logic, discrete hardware circuits, and other suitable hardware configured to perform the various functionality described throughout this disclosure. One or more processors in the processing system may execute software. Software shall be construed broadly to mean instructions, instruction sets, code, code segments, program code, programs, subprograms, software modules, applications, software applications, software packages, routines, subroutines, objects, executables, threads of execution, procedures, functions, etc., whether referred to as software, firmware, middleware, microcode, hardware description language, or otherwise. The software may reside on a computer-readable medium. A computer-readable medium may include, by way of example, a magnetic storage device (e.g., hard disk, floppy disk, magnetic strip), an optical disk (e.g., compact disk (CD), digital versatile disk (DVD)), a smart card, a flash memory device (e.g., card, stick, key drive), random access memory (RAM), read only memory (ROM), programmable ROM (PROM), erasable PROM (EPROM), electrically erasable PROM (EEPROM), a register, a removable disk, a carrier wave, a transmission line, and any other suitable medium for storing or transmitting software. The computer-readable medium may be resident in the processing system, external to the processing system, or distributed across multiple entities including the processing system. Computer-readable medium may be embodied in a computer-program product. By way of example, a computer-program product may include a computer-readable medium in packaging materials. Those skilled in the art will recognize how best to implement the described functionality presented throughout this disclosure depending on the particular application and the overall design constraints imposed on the overall system.

FIG. 1 is a conceptual diagram illustrating an example of a hardware implementation for an apparatus 100 employing a processing system 114. In this example, the processing system 114 may be implemented with a bus architecture, represented generally by the bus 102. The bus 102 may include any number of interconnecting buses and bridges depending on the specific application of the processing system 114 and the overall design constraints. The bus 102 links together various circuits including one or more processors, represented generally by the processor 104, and computer-readable media, represented generally by the computer-readable medium 106. The bus 102 may also link various other circuits such as timing sources, peripherals, voltage regulators, and power management circuits, which are well known in the art, and therefore, will not be described any further. A bus interface

108 provides an interface between the bus 102 and a transceiver 110. The transceiver 110 provides a means for communicating with various other apparatus over a transmission medium. Depending upon the nature of the apparatus, a user interface 112 (e.g., keypad, display, speaker, microphone, joystick) may also be provided.

The processor 104 is responsible for managing the bus 102 and general processing, including the execution of software stored on the computer-readable medium 106. The software, when executed by the processor 104, causes the processing system 114 to perform the various functions described infra for any particular apparatus. The computer-readable medium 106 may also be used for storing data that is manipulated by the processor 104 when executing software.

An example of a telecommunications system employing various apparatus will now be presented with reference to an LTE network architecture as shown in FIG. 2. The LTE network architecture 200 is shown with a core network 202 and an access network 204. In this example, the core network 202 provides packet-switched services to the access network 204, however, as those skilled in the art will readily appreciate, the various concepts presented throughout this disclosure may be extended to core networks providing circuit-switched services.

The access network 204 is shown with a single apparatus 212, which is commonly referred to as an evolved NodeB in LTE applications, but may also be referred to by those skilled in the art as a base station, a base transceiver station, a radio base station, a radio transceiver, a transceiver function, a basic service set (BSS), an extended service set (ESS), or some other suitable terminology. The eNodeB 212 provides an access point to the core network 202 for a mobile apparatus 214. Examples of a mobile apparatus include a cellular phone, a smart phone, a session initiation protocol (SIP) phone, a laptop, a personal digital assistant (PDA), a satellite radio, a global positioning system, a multimedia device, a video device, a digital audio player (e.g., MP3 player), a camera, a game console, or any other similar functioning device. The mobile apparatus 214 is commonly referred to as user equipment (UE) in LTE applications, but may also be referred to by those skilled in the art as a mobile station, a subscriber station, a mobile unit, a subscriber unit, a wireless unit, a remote unit, a mobile device, a wireless device, a wireless communications device, a remote device, a mobile subscriber station, an access terminal, a mobile terminal, a wireless terminal, a remote terminal, a handset, a user agent, a mobile client, a client, or some other suitable terminology.

The core network 202 is shown with several apparatus including a packet data node (PDN) gateway 208 and a serving gateway 210. The PDN gateway 208 provides a connection for the access network 204 to a packet-based network 206. In this example, the packet-based network 206 is the Internet, but the concepts presented throughout this disclosure are not limited to Internet applications. The primary function of the PDN gateway 208 is to provide the UE 214 with network connectivity. Data packets are transferred between the PDN gateway 208 and the UE 214 through the serving gateway 210, which serves as the local mobility anchor as the UE 214 roams through the access network 204.

An example of an access network in an LTE network architecture will now be presented with reference to FIG. 3. In this example, the access network 300 is divided into a number of cellular regions (cells) 302. An eNodeB 304 is assigned to a cell 302 and is configured to provide an access point to a core network 202 (see FIG. 2) for all the UEs 306 in the cell 302. There is no centralized controller in this example of an access network 300, but a centralized controller may be used in

5

alternative configurations. The eNodeB **304** is responsible for all radio related functions including radio bearer control, admission control, mobility control, scheduling, security, and connectivity to the serving gateway **210** in the core network **202** (see FIG. 2).

The modulation and multiple access scheme employed by the access network **300** may vary depending on the particular telecommunications standard being deployed. In LTE applications, OFDM is used on the DL and SC-FDMA is used on the UL to support both frequency division duplexing (FDD) and time division duplexing (TDD). As those skilled in the art will readily appreciate from the detailed description to follow, the various concepts presented herein are well suited for LTE applications. However, these concepts may be readily extended to other telecommunication standards employing other modulation and multiple access techniques. By way of example, these concepts may be extended to Evolution-Data Optimized (EV-DO) or Ultra Mobile Broadband (UMB). EV-DO and UMB are air interface standards promulgated by the 3rd Generation Partnership Project 2 (3GPP2) as part of the CDMA2000 family of standards and employs CDMA to provide broadband Internet access to mobile stations. These concepts may also be extended to Universal Terrestrial Radio Access (UTRA) employing Wideband-CDMA (W-CDMA) and other variants of CDMA, such as TD-SCDMA; Global System for Mobile Communications (GSM) employing TDMA; and Evolved UTRA (E-UTRA), Ultra Mobile Broadband (UMB), IEEE 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802.20, and Flash-OFDM employing OFDMA. UTRA, E-UTRA, UMTS, LTE and GSM are described in documents from the 3GPP organization. CDMA2000 and UMB are described in documents from the 3GPP2 organization. The actual wireless communication standard and the multiple access technology employed will depend on the specific application and the overall design constraints imposed on the system.

The eNodeB **304** may have multiple antennas supporting MIMO technology. The use of MIMO technology enables the eNodeB **304** to exploit the spatial domain to support spatial multiplexing, beamforming, and transmit diversity.

Spatial multiplexing may be used to transmit different streams of data simultaneously on the same frequency. The data streams may be transmitted to a single UE **306** to increase the data rate or to multiple UEs **306** to increase the overall system capacity. This is achieved by spatially precoding each data stream and then transmitting each spatially precoded stream through a different transmit antenna on the downlink. The spatially precoded data streams arrive at the UE(s) **306** with different spatial signatures, which enables each of the UE(s) **306** to recover the one or more the data streams destined for that UE **306**. On the uplink, each UE **306** transmits a spatially precoded data stream, which enables the eNodeB **304** to identify the source of each spatially precoded data stream.

Spatial multiplexing is generally used when channel conditions are good. When channel conditions are less favorable, beamforming may be used to focus the transmission energy in one or more directions. This may be achieved by spatially precoding the data for transmission through multiple antennas. To achieve good coverage at the edges of the cell, a single stream beamforming transmission may be used in combination with transmit diversity.

In the detailed description that follows, various aspects of an access network will be described with reference to a MIMO system supporting OFDM on the downlink. OFDM is a spread-spectrum technique that modulates data over a number of subcarriers within an OFDM symbol. The subcarriers

6

are spaced apart at precise frequencies. The spacing provides “orthogonality” that enables a receiver to recover the data from the subcarriers. In the time domain, a guard interval (e.g., cyclic prefix) may be added to each OFDM symbol to combat inter-OFDM-symbol interference. The uplink may use SC-FDMA in the form of a DFT-spread OFDM signal to compensate for high peak-to-average power ratio (PARR).

Various frame structures may be used to support the DL and UL transmissions. An example of a DL frame structure will now be presented with reference to FIG. 4. However, as those skilled in the art will readily appreciate, the frame structure for any particular application may be different depending on any number of factors. In this example, a frame (10 ms) is divided into 10 equally sized sub-frames. Each sub-frame includes two consecutive time slots.

A resource grid may be used to represent two time slots, each time slot including a resource block. The resource grid is divided into multiple resource elements. In LTE, a resource block contains 12 consecutive subcarriers in the frequency domain and, for a normal cyclic prefix in each OFDM symbol, 7 consecutive OFDM symbols in the time domain, or 84 resource elements. The number of bits carried by each resource element depends on the modulation scheme. Thus, the more resource blocks that a UE receives and the higher the modulation scheme, the higher the data rate for the UE.

The radio protocol architecture may take on various forms depending on the particular application. An example for an LTE system will now be presented with reference to FIG. 5. FIG. 5 is a conceptual diagram illustrating an example of the radio protocol architecture for the user and control planes.

Turning to FIG. 5, the radio protocol architecture for the UE and eNodeB is shown with three layers: Layer 1, Layer 2, and Layer 3. Layer 1 is the lowest layer and implements various physical layer signal processing functions. Layer 1 will be referred to herein as the physical layer **506**. Layer 2 (L2 layer) **508** is above the physical layer **506** and is responsible for the link between the UE and eNodeB over the physical layer **506**.

In the user plane, the L2 layer **508** includes a media access control (MAC) sublayer **510**, a radio link control (RLC) sublayer **512**, and a packet data convergence protocol (PDCP) **514** sublayer, which are terminated at the eNodeB on the network side. Although not shown, the UE may have several upper layers above the L2 layer **508** including a network layer (e.g., IP layer) that is terminated at the PDN gateway **208** (see FIG. 2) on the network side, and an application layer that is terminated at the other end of the connection (e.g., far end UE, server, etc.).

The PDCP sublayer **514** provides multiplexing between different radio bearers and logical channels. The PDCP sublayer **514** also provides header compression for upper layer data packets to reduce radio transmission overhead, security by ciphering the data packets, and handover support for UEs between eNodeBs. The RLC sublayer **512** provides segmentation and reassembly of upper layer data packets, retransmission of lost data packets, and reordering of data packets to compensate for out-of-order reception due to hybrid automatic repeat request (HARQ). The MAC sublayer **510** provides multiplexing between logical and transport channels. The MAC sublayer **510** is also responsible for allocating the various radio resources (e.g., resource blocks) in one cell among the UEs. The MAC sublayer **510** is also responsible for HARQ operations.

In the control plane, the radio protocol architecture for the UE and eNodeB is substantially the same for the physical layer **506** and the L2 layer **508** with the exception that there is no header compression function for the control plane. The

control plane also includes a radio resource control (RRC) sublayer **516** in Layer 3. The RRC sublayer **516** is responsible for obtaining radio resources (i.e., radio bearers) and for configuring the lower layers using RRC signaling between the eNodeB and the UE.

FIG. 6 is a block diagram of a eNodeB in communication with a UE in an access network. In the DL, upper layer packets from the core network are provided to a transmit (TX) L2 processor **614**. The TX L2 processor **614** implements the functionality of the L2 layer described earlier in connection with FIG. 5. More specifically, the TX L2 processor **614** compresses the headers of the upper layer packets, ciphers the packets, segments the ciphered packets, reorders the segmented packets, multiplexes the data packets between logical and transport channels, and allocates radio resources to the UE **650** based on various priority metrics. The TX L2 processor **614** is also responsible for HARQ operations, retransmission of lost packets, and signaling to the UE **650** based on controls from the TX radio resource controller **612**.

The TX data processor **616** implements various signal processing functions for the physical layer. The signal processing functions includes coding and interleaving to facilitate forward error correction (FEC) at the UE **650** and mapping to signal constellations based on various modulation schemes (e.g., binary phase-shift keying (BPSK), quadrature phase-shift keying (QPSK), M-phase-shift keying (M-PSK), M-quadrature amplitude modulation (M-QAM)). The coded and modulated symbols are then split into parallel streams. Each stream is then mapped to an OFDM subcarrier, multiplexed with a reference signal (e.g., pilot) in the time and/or frequency domain, and then combined together using an Inverse Fast Fourier Transform (IFFT) to produce a physical channel carrying a time domain OFDM symbol stream. The OFDM stream is spatially precoded to produce multiple spatial streams. Channel estimates from a channel estimator **674** may be used to determine the coding and modulation scheme, as well as for spatial processing. The channel estimate may be derived from a reference signal and/or channel condition feedback transmitted by the UE **650**. Each spatial stream is then provided to a different antenna **620** via a separate transmitter **618TX**. Each transmitter **618TX** modulates an RF carrier with a respective spatial stream for transmission.

At the UE **650**, each receiver **654RX** receives a signal through its respective antenna **652**. Each receiver **654RX** recovers information modulated onto an RF carrier and provides the information to the receiver (RX) data processor **656**.

The RX data processor **656** implements various signal processing functions of the physical layer. The RX data processor **656** performs spatial processing on the information to recover any spatial streams destined for the UE **650**. If multiple spatial streams are destined for the UE **650**, they may be combined by the RX data processor **656** into a single OFDM symbol stream. The RX data processor **656** then converts the OFDM symbol stream from the time-domain to the frequency domain using a Fast Fourier Transform (FFT). The frequency domain signal comprises a separate OFDM symbol stream for each subcarrier of the OFDM signal. The symbols on each subcarrier, and the reference signal, is recovered and demodulated by determining the most likely signal constellation points transmitted by the eNodeB **610**. These soft decisions may be based on channel estimates computed by the channel estimator **658**. The soft decisions are then decoded and deinterleaved to recover the data and control signals that were originally transmitted by the eNodeB **610** on the physical channel. The data and control signals are then provided to a RX L2 processor **660**.

The RX L2 processor **660** implements the functionality of the L2 layer described earlier in connection with FIG. 5. More specifically, the RX L2 processor **660** provides demultiplexing between transport and logical channels, reassembles the data packets into upper layer packets, deciphers the upper layer packets, decompresses the headers and processes the control signals. The upper layer packets are then provided to a data sink **662**, which represents all the protocol layers above the L2 layer. The RX L2 processor **660** is also responsible for error detection using an acknowledgement (ACK) and/or negative acknowledgement (NACK) protocol to support HARQ operations. The control signals are provided to a RX radio resource controller **661**.

In the UL, a data source **667** is used to provide data packets to a transmit (TX) L2 processor **664**. The data source **667** represents all protocol layers above the L2 layer (L2). Similar to the functionality described in connection with the DL transmission by the eNodeB **610**, the TX L2 processor **664** implements the L2 layer for the user plane and the control plane. The latter is in response to a TX radio resource controller **665**. The TX data processor **668** implements the physical layer. Channel estimates derived by a channel estimator **658** from a reference signal or feedback transmitted by the eNodeB **610** may be used by the TX data processor **668** to select the appropriate coding and modulation schemes, and to facilitate spatial processing. The spatial streams generated by the TX data processor **668** are provided to different antenna **652** via separate transmitters **654TX**. Each transmitter **654TX** modulates an RF carrier with a respective spatial stream for transmission.

The UL transmission is processed at the eNodeB **610** in a manner similar to that described in connection with the receiver function at the UE **650**. Each receiver **618RX** receives a signal through its respective antenna **620**. Each receiver **618RX** recovers information modulated onto an RF carrier and provides the information to a RX data processor **670**. The RX data processor **670** implements the physical layer and the RX L2 processor **672** implements the L2 layer. Upper layer packets from the RX L2 processor may be provided to the core network and control signals may be provided to a RX radio resource controller **676**.

FIG. 7 is a conceptual diagram illustrating a UE **708** receiving signals from a plurality of eNodeBs **702**, **704**, **706**. In some scenarios, a UE may need to connect to a weaker cell instead of the strongest cell. As an example, for range expansion, it may be beneficial to associate a UE with a weaker cell with smaller path loss even though the transmit power of that cell may be lower than the strongest cell. Furthermore, the strongest cell may be a closed subscriber group (CSG) cell and, therefore, may not be accessible to the UE.

In such scenarios, it may be beneficial for the UE to track the timing, carrier frequency, or both of the stronger cell instead of the weaker serving cell's. Conventionally, a UE's timing tracking loop (TTL) and frequency tracking loop (FTL) try to obtain serving cell timing and frequency. In certain scenarios, however, it may be beneficial that a UE tracks timing/frequency of the serving cell, timing/frequency of a dominant interferer, or combined timing/frequency of all cells, including the serving cell and all interferers. Benefits may include, for example, improved cancellation of signals from interfering cells.

As a UE tracks a single timing (be it a serving cell's timing, a strong interferer's timing, or a composite timing), there naturally exists a gap between the timing the UE is tracking (i.e., the timing of the UE with respect to the timing alignment of a frame, the subframes within the frame, and the OFDM symbols within each subframe) and the timing of each cell the

UE wants to monitor. For example, referring to FIG. 7, there may be a gap between the timing the UE 708 is tracking and the timing of each of the eNodeBs 702, 704, 706.

According to certain aspects presented herein, the UE 708 may track a single system timing and/or system frequency and estimate per-cell timing or frequency offsets for each cell. The system timing and/or frequency may be derived from a single cell (e.g., with a strongest receive signal strength) or from multiple cells. As a simple example, a first cell (e.g., “cell A” with eNodeB 702) may have a frequency of 2 GHz+100 Hz and a second cell (“cell B” with eNodeB 704) may have a frequency of 2 GHz+200 Hz. Assuming the UE 708 sees similar received powers from the two cells, the UE may want to track 2 GHz+150 Hz, and determine the per-cell frequency error of cell A as -50 Hz (relative to the tracked frequency of 2 GHz+150 Hz) and of cell B as +50 Hz. In other words, in this example, the UE 708 is not tracking the frequency of any particular cell, but rather it is tracking an average frequency of the two cells. Similarly, for timing tracking, a UE may track timing of a single cell or “composite” timing derived from the timing of multiple cells.

The per-cell timing offset of a cell may be estimated by using signals transmitted from the cell(s), such as a cell-specific reference signal (CRS), primary synchronization signal (PSS), secondary synchronization signal (SSS), or cyclic prefix (CP). The per-cell timing offset may be estimated concurrently, assuming the UE 708 has the appropriate duplicative hardware, or the offset may be estimated sequentially. The per-cell timing offset estimates may be used to enhance the performance of the UE 708, for example, by increasing accuracy of channel estimation between the UEs and different eNodeBs. In one configuration, the tracking with the particular timing is performed by combining signals from the cells. The signals include at least one of CRS tones, a PSS, an SSS, or a cyclic prefix. In one configuration, the signals are combined according to received strengths of the signals.

As noted above, as the UE 708 tracks the carrier frequency (or frequency error relative to a particular carrier frequency) of a single cell (be it a serving cell's or a strong interferer's) or a composite frequency offset, there exists a gap between the carrier frequency the UE 708 is tracking (i.e., the carrier frequency including the carrier frequency error to which the UE is tuned) and the carrier frequency error of each cell the UE 708 wants to monitor.

As such, according to certain aspects, the UE 708 may also estimate the per-cell frequency offset of each cell. The per-cell frequency offset of a cell is the offset between the carrier frequency (or frequency error) the UE is tracking (tuned to) and the frequency error of a particular cell the UE 708 is tracking. The per-cell frequency offset of a cell may also be estimated by using signals transmitted from the cell (e.g., RS tones, PSS, SSS, cyclic prefix, etc.). The per-cell frequency offset estimates may also be used to enhance the performance of the UE 708. Furthermore, the per-cell carrier frequency error estimates may be used to track a particular carrier frequency error. In one configuration, the tracking the particular carrier frequency error is performed by combining signals from the cells. The signals include at least one of CRS tones, a PSS, an SSS, or a cyclic prefix. In one configuration, the signals are combined according to received strengths of the signals.

In some cases, what the UE 708 may be tracking (estimating) is the error or deviation of the eNB's carrier frequency from the known carrier frequency value. For example, assume the carrier frequency is 2 GHz, which is known at the UE through a cell acquisition procedure. Assume also that the oscillator of eNodeB 704 is operating at 2 GHz+100 Hz and

the oscillator of eNodeB 706 is operating at 2 GHz+200 Hz. In this case, the mean carrier frequency error is 150 Hz, the carrier frequency error of the eNodeB 704 is 100 Hz, and the carrier frequency error of the eNodeB 706 is 200 Hz. Assume that the UE 708 is tracking the mean carrier frequency error of 150 Hz. As such, the frequency offset for the eNodeB 704 is 100 Hz minus 150 Hz, which is equal to -50 Hz, and the frequency offset for the eNodeB 706 is 200 Hz minus 150 Hz, which is equal to 50 Hz.

The per-cell timing offset can be used to better estimate the channel of each cell, as the per-cell timing enables the UE to accurately locate channel taps from the cell. For example, the UE 708 can set its channel tap truncation windows based on the per-cell timings. That is, the UE 708 can set a first channel tap truncation window based on the timing of the eNodeB 702, a second channel tap truncation window based on the timing of the eNodeB 704, and a third channel tap truncation window based on the timing of the eNodeB 706. For the serving cell, the improved channel estimation directly translates to improved UE performance. For an interfering cell, the improved channel estimation may translate to better interference cancellation of the cell and therefore improved UE performance. For example, if the eNodeB 702 is a serving cell for the UE 708 and the eNodeB 704 and the eNodeB 706 are interfering cells for the UE 708, the first channel tap truncation window will provide improved serving cell channel estimation. In addition, signals processed through the second and third channel tap truncation windows may lead to improved channel estimation between eNodeBs 704 and 706, which may result in better interference cancellation.

The per-cell frequency offset may also be used to better estimate the channel of each cell. For example, the UE 708 may apply a rotation (i.e., phase shift) on RS and channel estimates from a cell to help remove residual frequency error on the RS from the cell. The rotation amount may be determined based on the per-cell frequency offset estimate for the cell. For the serving cell, the improved channel estimation directly translates to improved UE performance. For an interfering cell, the improved channel estimation translates to better interference cancellation of the cell and therefore improved UE performance.

FIG. 8 illustrates example operations 800 for estimating per-cell timing offsets. The operations 800 may be performed, for example, by a UE, such as UE 708 shown in FIG. 7 to estimate per-cell timing offsets for eNodeBs 702-706.

The operations 800 begin, at 802, by estimating timing for tracking (e.g., the timing of a particular cell or a combination of a plurality of cells. As noted above, this timing may be derived from received signals (CRS, etc) from a strongest cell or by combining signals from multiple cells with appropriate averaging or weighting). At 804, per-cell timing offsets (relative to the aforementioned timing the UE is tracking) for all cells are determined. At 806, signals received from the plurality of cells are processed using one or more channel tap truncation windows set based on the timing offsets.

As described above, the timing offset for a cell generally refers to a difference between the timing for the cell and the timing a UE is tracking. According to certain aspects, a channel tap truncation window may be set for each cell based on the timing offset for that cell. According to certain aspects, a channel may be estimated from each cell through the channel tap truncation window for that cell. These estimated channels may be utilized in processing signals received from each cell.

FIG. 9 illustrates example operations 900 for estimating per-cell frequency offsets. The operations 900 may also be performed by a UE, such as UE 708 shown in FIG. 7 to estimate per-cell frequency offsets for eNodeBs 702-706.

11

The operations **900** begin, at **902**, by estimating a frequency of a particular cell or combination of a plurality of cells. As noted above, this frequency may be derived from received signals (CRS, etc) from a strongest cell or by combining signals from multiple cells with appropriate averaging or weighting). At **904**, per-cell frequency offsets (relative to the aforementioned carrier frequency the UE is tracking) for all cells are determined. At **906**, signals received from the plurality of cells are processed using the per-cell frequency offsets.

In one configuration, a particular carrier frequency that is tracked may be derived based on an average/mean of the per-cell frequency error estimates. As described above, the frequency offset for a cell generally refers to a difference between the carrier frequency (or frequency error) for the cell and the particular cell being tracked.

According to certain aspects, the processing of **906** may include applying a phase shift on cell-specific reference signals from each of the cells to remove a residual frequency error on the cell-specific reference signals. The phase shift on the cell-specific reference signals from a cell may be determined as a function of the determined frequency offset for that cell.

According to certain aspects, the frequency and/or timing offset averages may be weighted, for example, according to the received signal strengths of cells participating in the averaging.

FIG. **10** is a conceptual block diagram illustrating the functionality of an exemplary apparatus **1000**. The apparatus **1000** may include a module **1002** that estimates timing of a particular cell or combination of a plurality of cells, a module **1004** that determines per-cell timing offsets, relative to the timing the UE is tracking, for all cells of the plurality of cells, and a module **1006** that processes signals received from the plurality of cells by setting one or more channel tap truncation windows based on the per-cell timing offsets.

In addition to, or as an alternative to, the modules **1002-1006**, the apparatus **1000** may also include a module **1008** that determines per-cell frequency offsets, relative to the carrier frequency the UE is tracking, for all the plurality of cells, and a module **1010** that processes signals received from the plurality of cells based on the per-cell frequency offsets.

Depending on a particular configuration, an apparatus may utilize per-cell timing offsets, per-cell frequency offsets, or both. Thus, in one configuration, the apparatus **1000** may include modules **1002-1006**. In another configuration, the apparatus **1000** includes modules **1008-1012**. In yet another configuration, the apparatus **1000** may include modules **1002-1012**.

In one configuration, the apparatus **1000** for wireless communication may include means for performing the functionality shown in FIG. **10**. The means may comprise any suitable component or combination of components. According to certain aspects, the means may be implemented with the processing system **114** of FIG. **1**, configured to perform the functions described herein.

In cooperative multi-point (CoMP) systems, signals intended for a UE are transmitted from multiple cells (called "CoMP transmission points") and combined on the air. In some cases, the CoMP transmission points may be transparent to the UE, meaning the UE may not know which cells correspond to its CoMP transmission points. Transparency of the CoMP transmission points may be made possible by use of dedicated UE-specific RS (UE-RS).

FIG. **11** illustrates example operations **1100** for utilizing timing offsets in a CoMP system. The operations begin, at **1102**, by determining per-cell timing offsets, relative to the

12

timing of a particular cell, for remaining cells of a plurality of cells including CoMP cells. For example, these per-cell timing offsets may be determined as described above, with reference to FIG. **8**.

In order to accurately estimate the CoMP channel, the UE may identify the timings of cells in its CoMP transmission points. If CoMP transmission points are known to the UE, as determined at **1104**, the UE may calculate an average timing offset using timing offsets of those known CoMP cells, at **1106**. If CoMP transmission points are unknown to the UE, the UE may exclude timing offsets of known non-CoMP cells when calculating an average timing offset, at **1108**. Known non-CoMP cells may include certain cells that are not allowed to participate in a UE's CoMP. Examples of excludable cells may include cells where the UE is barred access (e.g., CSG cells).

The UE may set its channel tap truncation window based on the determined average timing offset (calculated for known CoMP transmission points and/or by excluding known non-CoMP transmission points).

As an example, referring to FIG. **7**, it may be assumed the eNodeB **702** and the eNodeB **704** are CoMP transmission points and the eNodeB **706** is not a CoMP transmission point. Assume also that the UE **708** is aware that the eNodeB **702** and the eNodeB **704** are CoMP transmission points and that the eNodeB **706** is not a CoMP transmission point. The UE **708** may estimate a timing offset for each of the cells **702**, **704**, **706**. In addition, the UE **708** may determine a timing offset for the CoMP transmission points **702**, **704** by combining signals of a subset of the cells. The subset of the cells includes cells **702**, **704**, as the UE **708** knows that these cells are CoMP transmission points. If the UE **708** did not know which cells are CoMP transmission points, the subset of the cells may include all the cells excluding cells known not to be CoMP transmission points. The UE **708** may set a channel tap truncation window for CoMP channel estimation based on the determined timing offset. The CoMP channel estimation is based on UE-specific reference signals from the CoMP transmission points **702**, **704**.

In order to accurately estimate the CoMP channel, the UE may additionally (or alternatively) identify the frequency offset of cells in its CoMP transmission points.

FIG. **12** illustrates example operations **1200** for utilizing frequency offsets in a CoMP system. The operations begin, at **1202**, by determining per-cell frequency offsets, relative to the frequency of a particular cell, for remaining cells of a plurality of cells including CoMP cells. For example, these per-cell frequency offsets may be determined as described above, with reference to FIG. **9**.

In order to accurately estimate the CoMP channel, the UE may identify the frequency of cells in its CoMP transmission points. If CoMP transmission points are known to the UE, as determined at **1204**, the UE may calculate an average frequency offset using frequency offsets of those known CoMP cells, at **1206**. If CoMP transmission points are unknown to the UE, the UE may exclude frequency offsets of known non-CoMP cells when calculating an average frequency offset, at **1208**.

The UE may use the average frequency offset to minimize the impact of frequency errors among CoMP transmission points. For example, the UE may attempt to minimize the impact of frequency errors by applying rotation on received UE-RS signals. That is, the UE may apply a phase shift on UE-specific reference signals from CoMP transmission points to minimize a residual frequency error on the UE-specific reference signals. The phase shift applied to the UE-

13

specific reference signals may be a function of the determined average carrier frequency offset.

The various operations of methods described above may be performed by any suitable means capable of performing the corresponding functions. The means may include various hardware and/or software component(s) and/or module(s), including, but not limited to a circuit, an application specific integrate circuit (ASIC), or processor.

The various illustrative logical blocks, modules and circuits described in connection with the present disclosure may be implemented or performed with a general purpose processor, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field programmable gate array signal (FPGA) or other programmable logic device (PLD), discrete gate or transistor logic, discrete hardware components or any combination thereof designed to perform the functions described herein. A general purpose processor may be a microprocessor, but in the alternative, the processor may be any commercially available processor, controller, micro-controller or state machine. A processor may also be implemented as a combination of computing devices, e.g., a combination of a DSP and a microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

The steps of a method or algorithm described in connection with the present disclosure may be embodied directly in hardware, in a software module executed by a processor, or in a combination of the two. A software module may reside in any form of storage medium that is known in the art. Some examples of storage media that may be used include random access memory (RAM), read only memory (ROM), flash memory, EPROM memory, EEPROM memory, registers, a hard disk, a removable disk, a CD-ROM and so forth. A software module may comprise a single instruction, or many instructions, and may be distributed over several different code segments, among different programs, and across multiple storage media. A storage medium may be coupled to a processor such that the processor can read information from, and write information to, the storage medium. In the alternative, the storage medium may be integral to the processor.

The methods disclosed herein comprise one or more steps or actions for achieving the described method. The method steps and/or actions may be interchanged with one another without departing from the scope of the claims. In other words, unless a specific order of steps or actions is specified, the order and/or use of specific steps and/or actions may be modified without departing from the scope of the claims.

The functions described may be implemented in hardware, software, firmware or any combination thereof. If implemented in software, the functions may be stored as one or more instructions on a computer-readable medium. A storage media may be any available media that can be accessed by a computer. By way of example, and not limitation, such computer-readable media can comprise RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage or other magnetic storage devices, or any other medium that can be used to carry or store desired program code in the form of instructions or data structures and that can be accessed by a computer. Disk and disc, as used herein, include compact disc (CD), laser disc, optical disc, digital versatile disc (DVD), floppy disk, and Blu-ray® disc where disks usually reproduce data magnetically, while discs reproduce data optically with lasers.

For example, such a device can be coupled to a server to facilitate the transfer of means for performing the methods described herein. Alternatively, various methods described herein can be provided via storage means (e.g., RAM, ROM,

14

a physical storage medium such as a compact disc (CD) or floppy disk, etc.), such that a user terminal and/or base station can obtain the various methods upon coupling or providing the storage means to the device. Moreover, any other suitable technique for providing the methods and techniques described herein to a device can be utilized.

It is to be understood that the claims are not limited to the precise configuration and components illustrated above. Various modifications, changes and variations may be made in the arrangement, operation and details of the methods and apparatus described above without departing from the scope of the claims.

While the foregoing is directed to aspects of the present disclosure, other and further aspects of the disclosure may be devised without departing from the basic scope thereof, and the scope thereof is determined by the claims that follow.

The invention claimed is:

1. A method of wireless communication by a user equipment (UE), comprising:

estimating a carrier frequency, wherein the estimated carrier frequency is derived from a frequency of one or more cells;

determining frequency offsets, relative to the estimated carrier frequency, for a plurality of the one or more cells including at least one serving cell; and

processing signals received from the plurality of cells based on one or more of the frequency offsets, the processing including

determining an average frequency offset from one or more of the determined frequency offsets; and

processing signals received from all or a subset of the plurality of cells based on the average frequency offset.

2. The method of claim 1, wherein the estimating the carrier frequency is performed by using a received signal comprising at least one of a cell-specific reference signal, a primary synchronization signal, a secondary synchronization signal, or a cyclic prefix.

3. The method of claim 2, wherein the received signal comprises a signal received from a particular cell.

4. The method of claim 3, wherein the particular cell comprises a cell with a strongest received signal strength for one or more reference signals.

5. The method of claim 4, wherein the received signal comprises a combination of signals from multiple cells.

6. The method of claim 4, further comprising applying a phase shift to a cell-specific reference signal from at least one of the plurality of cells, wherein the phase shift is a function of the determined frequency offset for the at least one of the plurality of cells.

7. The method of claim 1, wherein the subset of the plurality of cells includes cells known to participate in cooperative multi-point (CoMP) transmissions to the UE.

8. The method of claim 7, wherein:

determining the average frequency offset comprises utilizing frequency offsets for cells known to participate in CoMP transmissions.

9. The method of claim 7, wherein:

determining the average frequency offset comprises utilizing frequency offsets for one or more cells known to not participate in CoMP transmissions.

10. The method of claim 7, wherein:

determining the average frequency offset comprises calculating a weighted average according to received signal strengths.

11. An apparatus for wireless communication by a user equipment (UE), comprising:

15

means for estimating a carrier frequency, wherein the estimated carrier frequency is derived from a frequency of one or more cells;

means for determining frequency offsets, relative to the estimated carrier frequency, for a plurality of the one or more cells including at least one serving cell; and

means for processing signals received from the plurality of cells based on one or more of the frequency offsets, wherein the means for processing signals

determines an average frequency offset from one or more of the determined frequency offsets; and

processes signals received from all or a subset of the plurality of cells based on the average frequency offset.

12. The apparatus of claim 11, wherein the means for estimating the carrier frequency utilizes a received signal comprising at least one of a cell-specific reference signal, a primary synchronization signal, a secondary synchronization signal, or a cyclic prefix.

13. The apparatus of claim 12, wherein the received signal comprises a signal received from a particular cell.

14. The apparatus of claim 13, wherein the particular cell comprises a cell with a strongest received signal strength for one or more reference signals.

15. The apparatus of claim 14, wherein the received signal comprises a combination of signals from multiple cells.

16. The apparatus of claim 14, further comprising means for applying a phase shift to a cell-specific reference signal from at least one of the plurality of cells, wherein the phase shift is a function of the determined frequency offset for the at least one of the plurality of cells.

17. The apparatus of claim 11, wherein

the means for processing signals includes a means for determining the average frequency offset; and

the subset of the plurality of cells includes cells known to participate in cooperative multi-point (CoMP) transmissions to the UE.

18. The apparatus of claim 17, wherein:

the means for determining the average frequency offset comprises means for utilizing frequency offsets for cells known to participate in CoMP transmissions.

16

19. The apparatus of claim 17, wherein:

the means for determining the average frequency offset comprises means for utilizing frequency offsets for one or more cells known to not participate in CoMP transmissions.

20. The apparatus of claim 17, wherein:

the means for determining the average frequency offset comprises means for calculating a weighted average according to received signal strengths.

21. An apparatus for wireless communications, comprising:

at least one processor configured to,

estimate a carrier frequency, wherein the estimated carrier frequency is derived from a frequency of one or more cells;

determine frequency offsets, relative to the estimated carrier frequency, for a plurality of the one or more cells including at least one serving cell, and

process signals received from the plurality of cells based on one or more of the frequency offsets, the processing including

determining an average frequency offset from one or more of the determined frequency offsets; and

processing signals received from all or a subset of the plurality of cells based on the average frequency offset; and

a memory coupled with the at least one processor.

22. A computer program product comprising a non-transitory computer-readable storage medium having a set of instructions stored thereon, executable by a processor for:

estimating a carrier frequency, wherein the estimated carrier frequency is derived from a frequency of one or more cells;

determining frequency offsets, relative to the estimated carrier frequency, for a plurality of the one or more cells including at least one serving cell; and

processing signals received from the plurality of cells based on one or more of the frequency offsets, the processing including

determining an average frequency offset from one or more of the determined frequency offsets; and

processing signals received from all or a subset of the plurality of cells based on the average frequency offset.
